Kinematics
- Describes motion while ignoring the agents that caused the motion
- In these lectures we will consider motion in one dimension (along a straight line)
- We will use the particle model
  - A particle is a point-like object, has mass but infinitesimal size (i.e., the size is very very small)

Position
- Position is defined in terms of a **frame of reference**
  - One dimensional, so generally the x-axis or y-axis
  - The object’s position is its location with respect to the frame of reference
  - The frame can be stationary or moving
Position-Time Graph

- The position-time graph shows the motion of the particle (car).
- The smooth curve is an approximation as to what happened between the data points.

Displacement

- Defined as the change in position during some time interval.
  - Represented as \( \Delta x \) (pronounced as delta x).
  \[ \Delta x = x_f - x_i \] (final displacement – initial displacement).
  - SI units are meters (m), \( \Delta x \) can be positive or negative.
- Displacement may not be always be equal to distance. Distance refers to the length of a path followed by a particle. **Give an example of distance of 5 m but the corresponding displacement is 0.**

Vectors and Scalars

- Vector quantities need both magnitude (size or numerical value) and direction to completely describe them.
  - We use + and - signs to indicate vector directions.
- Scalar quantities are completely described by magnitude only.

Average Velocity

- The **average velocity** is rate (w.r.t. time) at which the displacement occurs.
  \[ v_{average} = \frac{\Delta x}{\Delta t} = \frac{x_f - x_i}{\Delta t} \]
- The dimensions for velocity are length / time, [L/T].
- The SI units are m/s, or ms\(^{-1}\).
- It is also the slope of the line (gradient of the tangent line) in the position – time graph.
Average Speed

- Speed is a scalar quantity
  - same units as velocity
  - total distance / total time
- The average speed is not necessarily the magnitude of the average velocity
- Give an example where average speed is 2 m/s and its corresponding velocity is 0.

Instantaneous Velocity

- The limit of the average velocity refers to that instance when the time interval becomes infinitesimally short (very very short), or when the time interval approaches zero
- The instantaneous velocity indicates what is happening at every point of time. The information includes the direction of movement and magnitude of velocity.

Instantaneous Velocity, equations

- The general equation for instantaneous velocity is

  \[ v_x = \lim_{\Delta t \to 0} \frac{\Delta x}{\Delta t} = \frac{dx}{dt} \]

  (the value of the limit when \( \Delta t \) tends to 0)

- The instantaneous velocity can be positive, negative, or zero

Instantaneous Velocity, graph

- The instantaneous velocity is the slope of the line tangent to the \( x \) vs. \( t \) curve
- This would be the green line
- The blue lines show that as \( \Delta t \) gets smaller, they approach the green line
**Some Tangent Values**

- \( \tan (45^\circ) = \frac{y}{x} = 1 \)
- \( \tan (0^\circ) = 0 \)
- \( \tan (90^\circ) = \infty \)

**Average Acceleration**

- Acceleration is the rate of change of the velocity
  \[
  \bar{a}_x = \frac{\Delta v_x}{\Delta t} = \frac{v_{xf} - v_{xi}}{\Delta t}
  \]
- Dimensions are \( \frac{L}{T^2} = \text{m/s}^2 \)
- SI units are m/s\(^2\)

**Instantaneous Acceleration**

- The instantaneous acceleration is the limit of the average acceleration as \( \Delta t \) approaches 0, which is the value of the constant when \( \Delta t \) tends to 0.
  \[
  a_x = \lim_{\Delta t \to 0} \frac{\Delta v_x}{\Delta t} = \frac{dv_x}{dt} = \frac{d^2x}{dt^2}
  \]

**Instantaneous Acceleration - graph**

- The slope of the tangent in the velocity vs. time graph is the acceleration.
- The green line represents the instantaneous acceleration.
- The blue line is the average acceleration.
Acceleration and Velocity, 1

- When an object’s velocity and acceleration are in the same direction, the object is speeding up
- When an object’s velocity and acceleration are in the opposite direction, the object is slowing down

Acceleration and Velocity, 2

- The car is moving with constant positive velocity (shown by red arrows maintaining the same size)
- Acceleration equals zero

Acceleration and Velocity, 3

- Velocity and acceleration are in the same direction
- Acceleration is uniform (blue arrows maintain the same length)
- Velocity is increasing (red arrows are getting longer)
- This shows positive acceleration and positive velocity

Acceleration and Velocity, 4

- Acceleration and velocity are in opposite directions
- Acceleration is uniform (blue arrows maintain the same length)
- Velocity is decreasing (red arrows are getting shorter)
- Positive velocity and negative acceleration
Kinematic Equations - summary

</tbody>
</table>

Note: Motion is along the x-axis.

Similar set of equations:

$v = u + at$
$s = s_0 + \frac{1}{2} (u + v)t$
$s = s_0 + ut + \frac{1}{2} at^2$
$v^2 = u^2 + 2a(s - s_0)$

$u$: initial velocity
$v$: final velocity
$s_0$: initial displacement
$s$: final displacement
$a$: acceleration

We will derive them!!

Linear Acceleration

Let
- Final velocity be $v$
- Initial velocity be $u$
- Distance travelled be $s$
- Acceleration be $a$
- Time duration be $t$

By definition:

\[ a = \frac{v - u}{t} \]
\[ at = v - u \]
\[ \therefore v = u + at \]

Let the small change in velocity be $\Delta v$ \[ \Rightarrow \Delta v = at \]
\[ \therefore v = u + \Delta v \]

i.e. final velocity = initial velocity + small change in velocity in the time interval $t$

Consider a constant velocity: $v = \frac{s}{t} \Rightarrow s = vt$

In $v$ vs. $t$ graph, $v \times t = \text{Area under the curve}$

i.e. the distance travelled is equal to the area under the curve of $v$ vs. $t$ graph.
Now consider a linear change in velocity in the following graph:

\[ \Delta v = at \]

Area under the curve = area of rectangle + area of triangle

\[ = ut + \frac{1}{2} (u + v)(at) \]

\[ \Rightarrow s = ut + \frac{1}{2} at^2 \]

If the starting distance is not 0, say \( s_0 \), we have

\[ s = s_0 + ut + \frac{1}{2} at^2 \]

The distance travelled due to linear acceleration can also be derived by the area of a trapezium:

\[ Area = \frac{\left( l_1 + l_2 \right) \times h}{2} \]

\[ \Rightarrow s = \frac{(u + v) \times t}{2} \]

Next, from \( v = u + at \), we have \( t = \frac{v - u}{a} \)

Substitute \( \frac{v - u}{a} \) into \( s - s_0 = ut + \frac{1}{2} at^2 \)

We have:

\[
\begin{align*}
  s - s_0 &= \frac{u(v - u)}{a} + \frac{a(v - u)^2}{2a^2} \\
  s - s_0 &= \frac{uv - u^2}{a} + \frac{a(v^2 - 2uv + u^2)}{2a^2} \\
  s - s_0 &= \frac{2uv - 2u^2}{2a} + \frac{v^2 - 2uv + u^2}{2a} \\
  s - s_0 &= \frac{v^2 - u^2}{2a} \\
  \Rightarrow 2a(s - s_0) &= v^2 - u^2 \\
  \text{If the starting point is at origin, i.e. } s_0 = 0 \\
  v^2 &= u^2 + 2as
\end{align*}
\]

Kinematic Equations

- The kinematic equations may be used to solve any problem involving one-dimensional motion with a constant acceleration
- Sometime you may need to use two of the equations to solve one problem
- Many times there is more than one way to solve a problem
Kinematic Equations, specific

- For constant $a$, $v_{xf} = v_{xi} + a_x t$
- We can determine an object’s velocity at any time $t$ when we know its initial velocity and its acceleration
- It does not give any information about displacement

For constant acceleration,

- $\bar{v}_x = \frac{v_{xi} + v_{xf}}{2}$
- The average velocity can be expressed as the arithmetic mean of the initial and final velocities

This equation gives us the position of the particle in terms of time and velocities

- The equation doesn’t give us the acceleration

For constant acceleration,

- $x_f = x_i + v_{xi} t + \frac{1}{2} a_x t^2$
- This equation gives final position in terms of velocity and acceleration
- It doesn’t tell you about final velocity
Kinematic Equations, specific

- For constant $a$,
  \[ v_{xf}^2 = v_{xi}^2 + 2a(x_f - x_i) \]
- This equation gives final velocity in terms of acceleration and displacement.
- It does not give any information about the time.

Graphical Look at Motion – Position - time curve (graph)

- The slope of the curve is the velocity.
- The curved line indicates that the velocity is changing.
  - Therefore, there is an acceleration.

What if the curve in the Position-Time graph is a horizontal straight line?

Answer: The object is not moving, i.e., velocity = 0.

Graphical Look at Motion – velocity - time curve

- The slope gives the acceleration.
- The straight line in velocity – time graph indicates a constant acceleration, which can be 0 if it is a horizontal line.

Answer: The object is moving with constant velocity, i.e., no acceleration.
The zero slope in acceleration – time graph indicates a constant acceleration.

**Example:** Speedy Sue, driving at 30.0 m/s, enters a one-lane tunnel. She then observes a slow-moving van 155 m ahead traveling at 5.00 m/s. Sue applies her brakes but can accelerate only at $-2.00 \text{ m/s}^2$ because the road is wet. Will there be a collision? If yes, determine how far into the tunnel and at what time the collision occurs. If no, determine the distance of closest approach between Sue’s car and the van.

- **Sue:** $v_{0} = 30.0 \text{ m/s}$, $a_{y} = -2.00 \text{ m/s}^2$
- **Van:** $v_{0} = 5.00 \text{ m/s}$

**Answer:**

$$\text{Take the original point to be when Sue notices the van. Choose the origin of the x-axis at Sue’s car. For her we have } x_{0} = 0, \ v_{x} = 30.0 \text{ m/s}, \ a_{x} = -2.00 \text{ m/s}^2 \text{ so her position is given by}$$

$$x(t) = x_{0} + v_{x}t + \frac{1}{2} a_{x}t^2 = (30.0 \text{ m/s})t + \frac{1}{2}(-2.00 \text{ m/s}^2)t^2.$$

For the van, $x_{v} = 155 \text{ m}$, $v_{v} = 5.00 \text{ m/s}$, $a_{v} = 0$ and

$$x(t) = x_{v} = v_{x}t + \frac{1}{2} a_{v}t^2 = 155 + 5.00 \text{ m/s} \cdot t.$$

To test for a collision, we look for an instant $t$ when both are at the same place:

$$30.0t - \frac{t^2}{2} = 155 + 5.00t,$$

$$0 = \frac{t^2}{2} - 25.0t + 155.$$

From the quadratic formula,

$$t = \frac{-25.0 \pm \sqrt{(25.0)^2 - 4(155)}}{2} = 13.0 \text{ s or } 11.4 \text{ s}.$$

**Freely Falling Objects**

- A **freely falling object** is any object moving freely under the influence of gravity alone.
- It does not depend upon the initial motion of the object, which can be:
  - Dropped – released from rest
  - Thrown downward
  - Thrown upward
Acceleration of Freely Falling Object

- The acceleration of an object in free fall is directed downward, regardless of the initial motion.
- The magnitude of free fall acceleration is $g = 9.80 \text{ m/s}^2$.
- $g$ varies slightly at different geographical locations.
- $9.80 \text{ m/s}^2$ is the average at the Earth’s surface.

Acceleration of Free Fall, cont.

- We will neglect air resistance.
- Free fall motion is constantly accelerated motion in one dimension.
- Let upward be positive, so downward is negative.
- Use the kinematic equations with $a_y = g = -9.80 \text{ m/s}^2$.

Free Fall Example

- Initial velocity at A is upward (+) and acceleration is $g (-9.8 \text{ m/s}^2)$.
- At B, the velocity is 0 and the acceleration is $g (-9.8 \text{ m/s}^2)$.
- At C, the velocity has the same magnitude as at A, but is in the opposite direction.
- The displacement is $-50.0 \text{ m}$ (it ends up $50.0 \text{ m}$ below its starting point).

Motion Equations from Calculus

- Displacement equals the area under the velocity – time curve:
  $\lim_{\Delta t \to 0} \sum v_n \Delta t_n = \int_{t_i}^{t_f} v_x(t)dt$.
- The limit of the sum is a definite integral.
Kinematic Equations – General Calculus Form

\[ a_x = \frac{dv_x}{dt} \]

\[ v_{xf} - v_{xi} = \int_0^t a_x \, dt \]

\[ v_x = \frac{dx}{dt} \]

\[ x_f - x_i = \int_0^t v_x \, dt \]

Example: A baseball is hit so that it travels straight upward after being struck by the bat. A fan observes that it takes 3.00 s for the ball to reach its maximum height. Find (a) its initial velocity and (b) the height it reaches.

Answer:

(a) \( v_f = v_i - gt \); \( v_f = 0 \) when \( t = 3.00 \text{ s} \), \( g = 9.80 \text{ m/s}^2 \). Therefore,

\[ v_i = gt = (9.80 \text{ m/s}^2) (3.00 \text{ s}) = 29.4 \text{ m/s} \]

(b) \( y_f - y_i = \frac{1}{2} (v_f + v_i) t \)

\[ y_f - y_i = \frac{1}{2} (29.4 \text{ m/s}) (3.00 \text{ s}) = 44.1 \text{ m} \]

Kinematic Equations – Calculus Form with Constant Acceleration

- The integration form of \( v_f - v_i \) gives

\[ v_{xf} - v_{xi} = a_x t \quad v = u + at \], or \( v - u = at \)

- The integration form of \( x_f - x_i \) gives

\[ x_f - x_i = v_{xi} t + \frac{1}{2} a_x t^2 \quad s = s_0 + ut + \frac{1}{2} at^2 \], or \( s - s_0 = ut + \frac{1}{2} at^2 \)

Example: Two stones are released from rest at a certain height, one after the other at an interval of \( c \) seconds.

(a) Will the difference in their speeds increase, decrease, or stay the same?

Answer:

Let \( v_1 \) be the speed of first stone, and \( v_2 \) the speed of second stone. We have

\( v_1 = 0 - gt \)

\( v_2 = 0 - g(t-c) \);

\[ v_1 - v_2 = -gt + g(t-c) = -gc \quad \text{constant w.r.t. time} \]
(b) Will their separation distance increase, decrease or stay the same?

Answer:
Let \( s_1 \) be the displacement of first stone, and \( s_2 \) the displacement of second stone. We have:

\[
\begin{align*}
    s_1 &= 0 - \frac{1}{2}gt^2 \quad \text{for } t > 0 \\
    s_2 &= 0 - \frac{1}{2}g(t - c)^2 \quad \text{for } t > c
\end{align*}
\]

\[
s_1 - s_2 = -\frac{1}{2}gt^2 + \frac{1}{2}g(t - c)^2
\]

\[
= -\frac{1}{2}gt^2 + \frac{1}{2}g(t^2 - 2tc + c^2)
\]

\[
= \frac{1}{2}g(-2tc + c^2)
\]

**absolute difference is increasing w.r.t. time**

---

(c) Will the time interval between the instants at which they hit the ground be smaller than, equal to, or larger than the time interval between the instants of their release?

Answer:
Let \( t_1 \) be the time for the first stone to hit the ground, and \( t_2 \) the time for the second stone to hit the ground. Let the height be \( h \). We have:

\[
-h = 0 - \frac{1}{2}gt_1^2
\]

\[
t_1^2 = \frac{2h}{g}
\]

\[
t_2 = c + \sqrt{\frac{2h}{g}}
\]

\[
t_1 = \sqrt{\frac{2h}{g}}
\]

*Therefore \( t_2 - t_1 = c \) (same as the difference of the instants of their release.)*

---

**Example:** A small piece of light paper and a metal coin are dropped from the same height in the air at the same time. Which item will reach the ground first?

**Answer:**
The metal coin will reach the ground first.

Is the acceleration due to gravity experienced by the small piece of paper is smaller (as it takes a longer time to reach the ground) than that experienced by the metal coin?

**Answer:**
No. The acceleration due to gravity is the same for both items. But the net acceleration is not the same due to the relative amount of upthrust provided by the air as compared to the weight of the object. The upthrust due to the air is more significant on the paper than on the coin.

**Example:** What if the paper is on top of a metal plate and all the 3 items are released at the same time?

**Answer:**
The metal plate has removed the air volume below the paper during the free fall so the paper and the coin will reach the ground at the same time. There is almost no upthrust due to the air on the paper.
How to make the paper and coin hit the floor at the same time without the help of metal plate, container and air pump?

**Answer:**

Ask a magician to do it.
